COMPLETE SPECIFICATION

"SCORED FIBERBOARD HAVING IMPROVED MOLDABILITY"

We, MASONITE CORPORATION, a corporation of the State of Delaware, United States of America, of One South Wacker Drive, Chicago, Illinois 60606, United States of America

hereby declare the invention for which we pray that a patent may be granted to us,
and the method by which it is to be performed, to be particularly described in and
by the following statement:-

(followed by page 1a)

BACKGROUND OF THE INVENTION5 Field of the Invention

This invention relates to the molding of a composite board of cellulosic fibers between matched die sets to produce a high density, three dimensional board free of stretch marks and fractures. According to the
10 invention, hardboard door facings may be molded with a high degree of fidelity to the contours and angles of the die set bearing the pattern of the desired profile.

Description of Related Technology

15 The fibers of a rigid fiberboard, made by the consolidation of a water-felted mat under heat and pressure, are bound together primarily by hydrogen bonding and mechanical interlocking but also by the lignin native to the fibers. Such a fiberboard is
20 difficult to consolidate into thin, non-planar panels without causing stretch marks and even fractures in deeply molded regions or regions adjacent thereto. In a molding press, the tension and compression forces pull and push the fibers in a rigid fiberboard apart,
25 sometimes to the breaking point. This is a particularly significant problem with fiberboards having little or no resinous binders which would flow in response to said forces to take the place of the relatively inelastic fibers which cannot flow around the contours and angles
30 of the die set.

The fibers of a dry felted wood fiber mat, on the other hand, are loosely bound together by a synthetic thermosetting resin and can flow along with the resin during hot pressure molding.

35

C. C. Heritage teaches a method for improving the surfaces and strengthening contoured parts of a molded hardboard panel in Canadian Patent No. 572,073. Either dry- or water-felted wood fibers may be consolidated and molded to produce contoured hardboard, according to Heritage, by covering felted mats with an overlay of a thermoplastic or thermosetting resin in the form of a film, an impregnated fabric, or a coating.

According to the teachings of Nishibori in U.S. Patent No. 4,610,900, there is a problem when a synthetic resin is mixed with a cellulosic aggregate prior to molding. The aggregate, such as pulverized wood chips, is added to the resin to prevent the residual internal stress in the molded product which leads to warping and twisting thereof. Large amounts of the cellulosic aggregate, however, hamper the flowability of the resin and produce internal stresses in the resin product to be molded. Nishibori solves the problem by: first, heating and cooling the resin product; second, removing a skin layer of resin from the surface of the product by sanding or sandblasting; and third, cutting grooves out of the resulting exposed surface. This last operation suffers from the disadvantages of loss of the material removed to make the grooves and the expense of waste collection and removal.

SUMMARY OF THE INVENTION

It is an object of the invention to overcome one or more of the problems described above.

5 The invention provides a simple, non-destructive, and relatively inexpensive method of improving the moldability of consolidated fiberboards, especially water-felted wood fiberboards.

10 The invention also provides a rigid board of consolidated fibers which may be molded under pressure to a three dimensional board with high fidelity to the contours and angles of the mold.

15 The invention further provides an improved method of producing deeply molded hardboard from consolidated, water-felted wood fiberboards whereby the molded hardboard is free from stretch marks and tears or fractures.

According to one aspect of the invention, the subject of New Zealand Patent Specification No. 230209, one or more of the foregoing objectives is accomplished by providing a board of consolidated fibers comprising a major face with a selected area to be molded, an obverse face, and a plurality of discontinuous incisions on each of said faces. Preferably, the board of consolidated fibers is molded into a non-planar board, and preferably at least some of the fibers are severed with the ends of the severed fibers being substantially contiguous.

The invention also comprehends an apparatus for cutting discontinuous incisions into the face of a board.

According to another aspect of the invention, the subject of this specification, one or more of the foregoing objectives is accomplished by providing a method of molding a non-planar board comprising the steps of:

providing a dry board of consolidated fibers;

making a plurality of discontinuous incisions in a surface region of a selected area to be molded of at least one face of said dry board; and

compressing said dry board with a die set bearing a pattern of a desired profile.

Further objects and advantages of the invention will be apparent to those skilled in the art from a review of the following detailed description, taken in conjunction with the drawings and the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

For a fuller understanding of this invention, reference should be made to the drawings, in which:

FIG. 1 is a perspective view of a fiberboard having discontinuous incisions therein in accordance with the invention.

FIG. 2 is a partially cut away perspective view of a fiberboard having discontinuous incisions being made into its upper surface parallel to its longitudinal edges as it moves under an assembly of co-axially mounted, toothed cutting disks.

FIG. 3 is a top plan view of the apparatus of FIG. 2 in association with a similar apparatus set at right angles thereto.

FIG. 4 is a side view of the fiberboard and apparatus of FIG. 2.

FIG. 5 is an enlarged cross section of a board of this invention showing cuts in its surface region.

FIG. 6 is a photograph of a deeply molded hardboard made from the incised fiberboard of this invention.

FIG. 7 is a photograph of a deeply molded hardboard made from a fiberboard of the prior art having no incisions.

DETAILED DESCRIPTION OF THE INVENTION

According to the invention, a plurality of discontinuous incisions are made into the surface region of a major face of a fiberboard to sever fibers in the surface region without removing the fibers or other material therefrom, followed by molding the fiberboard. For the purposes of this invention, the surface region of a major face of the fiberboard extends inwardly for about one-third of the board's thickness. The discontinuous incisions define a line and may be made with a razor blade or similarly sharp cutting instrument having a thin blade, but it is preferred to use a cutting disk having circumferentially spaced notches in the blade.

The fiberboard may be a dry, consolidated mass of cellulosic fibers such as paper pulp, wood fibers, or other lignocellulosic fibers. Its density is typically in the range of about 10 to about 28 lbs. per cubic foot, preferably up to about 22 lbs. per cubic foot. The invention is particularly advantageous in the molding of fiberboards made from long fibers such as redwood fibers. Although one important objective of the invention is to improve the moldability of wet-felted rigid fiberboards having no added binder, the invention is operative with fiberboards containing conventional binders such as resins, starch, tung oil and the like.

In FIG. 1, a scored fiberboard 10 defines upper and lower major faces 11 and 12, respectively, and longitudinal edges 13. Intermittent incisions 14 in the face 11 lie along imaginary lines parallel to the longitudinal edges 13 and intermittent incisions 15 lie along imaginary lines perpendicular to those edges. Fibers in the surface region of the board are severed but are not removed from the board. The severed ends of the fibers are displaced initially by the thin blade of

a cutting instrument but the consequent compression of the adjacent masses of fiber and binder is relieved somewhat as the blade is removed and as the severed ends of the fibers move back to substantially contiguous positions in response to that compression.

5 A board having intermittent incisions in only one direction, i.e., along one or more lines parallel to or perpendicular to a longitudinal edge is useful when a design on the molded hardboard formed therefrom is to be
10 unidirectional. Generally, however, it is preferred to make incisions along intersecting lines so that the board is adapted to improved moldability regardless of the orientation of the design on the die set. The intersecting sets of parallel lines defined by the
15 incisions and the discontinuities therebetween are shown in FIG. 1 at right angles to one another but they may meet at acute angles. An advantage of the grid shown is the relative ease of designing and operating an apparatus for scoring a continuously moving board at
20 right angles to the direction of movement as opposed to acute angles. The illustration in FIG. 1 of a grid of incisions on various portions of the face 11 is representative of a grid extending over the entire face of the board. It will also be understood that the face
25 12 may be incised in like manner.

The discontinuities 16 or intervals of uncut surface between incisions along the imaginary lines have a maximum length of about 0.5 inch but they must be at least about 0.1 inch long. It is these intervals of
30 uncut fibers that preserve the integrity of the face of the board during the molding operation. It has been found that when continuous parallel incisions are made in a dry, water-felted board, the severed fibers pulled apart during the molding operation, leaving gaps in the surface of the molded board which gave it an unsightly,
35 unacceptable appearance.

In FIG. 2, a fiberboard 20 is moved by a conveyor belt 21 into engagement with a rotating cylinder-like assembly 22 of toothed cutting disks 23 which are mounted co-axially in spaced-apart relation on a shaft 24 which is driven by a motor 25 in the direction indicated by an arrow A. The longitudinal incisions 14 are made as the deltoid teeth or blades 26 cut into the surface region of the face 11, as shown more clearly in FIG. 4.

As mentioned above, the incisions may be made by a razor blade, severance rather than separation of the fibers being a critical feature of this method, along with the intermittency of the incisions. Because of the limitations of strength of extremely thin blades, however, the blades 26 are preferably wedge-shaped, having a thickness of as much as about 0.1 inch at their origin on the disk 23 and a razor-thin cutting edge.

In FIG. 3, the transversely oriented incisions 15 are cut into the face 11 after the longitudinally oriented incisions 14 have been made. The board 20 is moved by the conveyor belt 21 onto a conveyor belt 27 which is activated when the leading edge of the board 20 has traversed the width of the belt 27 and bumped a trigger switch 28. The board 20 is then carried along a path at right angles to the belt 21 so that an assembly 22a of cutting disks may make the incisions 15. The fiberboard 10 is the product.

Several alternatives to an assembly of cutting disks are contemplated for use as the cutting apparatus of this invention, among which is a metal cylinder having multiple blades formed around its circumference by a machining operation. Such blades may be axially aligned for cutting the intermittent incisions 15 perpendicular to the longitudinal edges of the fiberboard or circumferentially aligned for cutting the intermittent incisions 14. The circumferentially

aligned blades may have arcuate cutting edges instead of the saw tooth shape of the blades 26 but have divergent leading and trailing edges similar to those of the blades 26.

5 The depth and spacing of the incisions 14 are shown in FIG. 5. The depth of the incisions in each face of the fiberboard may be from about 10% to about 30% or even up to about one-third of the thickness of the board. For example, a 0.75 inch thick board may
10 have incisions about 0.25 inch deep in the face which is to be pressed inwardly by the die having the negative of the desired profile. If the appearance of the obverse face of the molded hardboard is important, both faces will be incised to a depth appropriate to the contours
15 and angles of the die set. The spacing between the parallel paths of the incisions 14 (and of the incisions 15) may be as large as about 0.5 inch but the fidelity of molding and the avoidance of stretch marks are better served by closer spacing, down to as little as about 0.1
20 inch or even less. It is preferred that a line of incisions in the board's face is generally oriented in the same direction as the margin of the design on a die and is located on the face so that there will be no more than about 0.25 inch between that line and the locus of
25 contact points made by a die when the die set is closed upon the fiberboard.

Conventional conditions of temperature and pressure may be used for the deep molding of the scored fiberboard between matched die sets. A breathe press
30 cycle is preferred over constant pressure. The surface of the scored fiberboard may be sprayed very lightly with water or an aqueous solution containing 20 wt.% urea and 10 wt.% of Glidden's Fibertight sealer, or equivalent materials, just prior to molding. The
35 specific gravity of the molded hardboard is about 1.0-1.2 and the internal bond strength is 100-200 psi.

Molded hardboards 60 and 70 of FIGS. 6 and 7, respectively, were made under substantially the same conditions from redwood fiberboards.

A comparison of the hardboard 60 made
5 according to the invention and the hardboard 70 made
according to the prior art demonstrates the superiority
of the product made from the incised fiberboard of this
invention. Stretch marks 72, clearly visible in the
board 70, are absent from the board 60. These stretch
10 marks are visible as fuzzy lines even on a painted
hardboard because of the uneven response to the paint.

It will be appreciated that the invention may
be practiced in various ways within the spirit and scope
of the following claims.

15

20

25

30

35

WHAT WE CLAIM IS:

1. A method of molding a non-planar board comprising the steps of:
 providing a dry board of consolidated fibers;
 making a plurality of discontinuous incisions in a surface region of a selected area to be molded of at least one face of said dry board; and
 compressing said dry board with a die set bearing a pattern of a desired profile.
2. The method of claim 1 wherein:
 said dry board is provided by water-felting and consolidating fibers to make a fiberboard and drying the fiberboard; and
 said dry board is compressed with a heated die set bearing a pattern of the desired profile.
3. The method of claim 2 wherein said incisions are made along intersecting lines.
4. The method of claim 2 wherein said incisions sever fibers in said surface region and leave the ends of said severed fibers substantially in place.
5. The method of claim 1 wherein said incisions sever fibers in said surface region and leave the ends of said severed fibers substantially in place.
6. The method of claim 5 wherein said incisions are made to a depth of from substantially 10% to substantially 30% of the thickness of said dry board.
7. The method of claim 5 wherein at least some of said incisions are substantially oriented within a margin of said pattern and are laterally disposed no more than substantially 0.25 inches from points where said dry board is molded.

8. The method of claim 5 wherein said incisions are made in substantially the entirety of said face.

9. The method of claim 5 wherein at least some of said incisions are made along at least one straight line.

10. The method of claim 9 wherein discontinuities between incisions on said line are substantially a maximum of substantially 0.5 inches long.

11. The method of claim 9 wherein at least some of said incisions are made along a plurality of parallel straight lines spaced a maximum of about 0.5 inches apart.

12. The method of claim 9 wherein at least some of said incisions are made along a plurality of intersecting straight lines.

13. The method of claim 9 wherein at least some of said intersecting lines are at right angles.

14. A non-planar board made by the method comprising the steps of:

providing a dry board of consolidated fibers;

making a plurality of discontinuous incisions in a surface region of at least one face of said dry board in a selected area to be molded, in order to sever fibers in said surface region and leaving the severed ends of said fibers substantially in place; and

compressing said dry board with a die set bearing a pattern of a desired profile.

15. A method as claimed in any one of claims 1 to 13 substantially as herein described.

247463

- 12 -

16. A non-planar board when made by the method of any one of claims 1 to 13 and 15.

17. A non-planar board as claimed in claim 14 substantially as herein described.
